Reference Guide

Below is a comprehensive reference guide for the Python programming language. It covers the core syntax, built-in functions, and standard library modules that you will use most often when writing scripts and applications.

Variables and Data Types

Python is dynamically typed, so you do not declare the type of a variable before assigning to it. The interpreter infers the type from the value on the right-hand side of the assignment. The most common built-in types are integers, floating-point numbers, strings, booleans, lists, tuples, dictionaries, and sets.

```
count = 42
ratio = 3.14159
name = "Ada Lovelace"
is_active = True
items = [1, 2, 3]
point = (10, 20)
config = {"host": "localhost", "port": 8080}
unique = {1, 2, 3}
```

You can check the type of any value with the `type()` function, and you can convert between types with constructors such as `int()`, `float()`, `str()`, `list()`, and `dict()`. Conversions that lose information, such as `int(3.9)`, truncate rather than round.

Control Flow

Conditional execution uses `if`, `elif`, and `else`. Loops use `for` and `while`. Indentation is significant and must be consistent; the conventional choice is four spaces per level. The `break` statement exits the innermost loop, and `continue` skips to the next iteration.

```
for n in range(10):
    if n % 2 == 0:
        print(n, "is even")
    else:
        print(n, "is odd")
```

Functions

Functions are defined with `def` and can take positional arguments, keyword arguments, default values, and variable-length argument lists. They return values with `return`; a function that reaches the end without a `return` statement returns `None`.

```
def greet(name, greeting="Hello"):
    return f"{greeting}, {name}!"

print(greet("Ada"))
print(greet("Ada", greeting="Bonjour"))
```

Modules and Packages

A module is a single `.py` file; a package is a directory containing modules and an `__init__.py` file. Use `import` to bring a module into scope, and `from ... import ...` to bring specific names into the current namespace. The standard library ships with hundreds of modules for tasks such as file I/O, networking, date handling, and testing.

Error Handling

Exceptions are raised with `raise` and caught with `try` / `except`. You can catch specific exception types, multiple types, or all exceptions. The `finally` clause runs whether or not an exception occurred, and is the right place for cleanup code such as closing files.

```
try:
    value = int(input("Enter a number: "))
except ValueError:
    print("That was not a number.")
finally:
    print("Done.")
```

Further Reading

For the full language reference, see the official documentation at docs.python.org. For a gentler introduction, the tutorial that ships with the interpreter walks through each of these topics in more depth, with exercises and examples.
